#### LECTURE OVERVIEW

- Variational Inference
- Mean-field variational inference
- ► Stochastic Variational Inference
- ► Black-Box Variational Inference

## VARIATIONAL INFERENCE (VI)

- $\blacktriangleright$  Let  $\theta = (\theta_1, ..., \theta_p)^T$ .
- $\blacktriangleright$  Aim: approximate posterior  $p(\theta|y)$  with a simpler distribution  $q(\theta)$ .
- ▶ Normal approximation:  $q(\theta) = N[\tilde{\theta}, -H^{-1}(\tilde{\theta})]$ , where  $\tilde{\theta}$  is the mode, and  $H^{-1}(\tilde{\theta})$  Hessian of log posterior at  $\tilde{\theta}$ .
- Normal approximation turns an inference problem into an optimization problem. VI does the same.
- **Variational Inference**: find  $q(\theta) \in \mathcal{Q}$  that is closest to the posterior  $p(\theta|\mathbf{x})$  in Kullback-Leibler sense

$$q^{\star}(\theta) = \mathop{\arg\min}_{q(\theta) \in \mathcal{Q}} \mathrm{KL}\left[q(\theta)||p(\theta|\mathbf{x})\right]$$

where

$$\mathrm{KL}\left[q(\theta)||p(\theta|\mathbf{x})\right] = \mathbb{E}_{q(\theta)}\log\left(\frac{q(\theta)}{p(\theta|\mathbf{x})}\right)$$

#### VARIATIONAL INFERENCE (VI)

▶ But ...

$$\mathrm{KL}\left[q(\theta)||p(\theta|\mathbf{x})\right] = \mathbb{E}_{q(\theta)}\log q(\theta) - \mathbb{E}_{q(\theta)}\log p(\theta|\mathbf{x})$$

is intractable since  $\mathbb{E}_{q(\theta)} \log p(\theta|\mathbf{x}) = \mathbb{E}_{q(\theta)} \log p(\mathbf{x}, \theta) - \log p(\mathbf{x})$ .

▶ But  $\log p(x)$  is just a constant, so we can instead maximize **Evidence** Lower BOund (ELBO):

$$\mathrm{ELBO}(q) = \mathbb{E}_{q(\theta)} \log p(\mathbf{x}, \theta) - \mathbb{E}_{q(\theta)} \log q(\theta)$$

▶ ELBO is a lower bound for the (log) evidence (marginal likelihood) since  $KL \ge 0$  and

$$\log p(\mathbf{x}) = \mathrm{KL}\left[q(\theta)||p(\theta|\mathbf{x})| + \mathrm{ELBO}(q).$$

Forward KL vs Backward KL.

#### MEAN FIELD APPROXIMATION

VI turns inference into a optimization problem

$$q^{\star}(\theta) = \mathop{\mathrm{arg\,max}}_{q(\theta) \in \mathcal{Q}} \mathrm{ELBO}(q)$$

- ▶ Large  $Q \Rightarrow$  accurate approximation, hard optimization.
- ▶ Small  $Q \Rightarrow$  crude approximation, easy optimization.
- ► Mean-field Variational Inference (MFVI) uses the factorization

$$q(\theta) = \prod_{i=1}^p q_i(\theta_i)$$

- ▶ No specific functional forms are assumed for the  $q_i(\theta)$ .
- ▶ Optimal densities can be shown to satisfy [1]

$$q_i(\theta) \propto \exp(E_{-\theta_i} \ln p(\mathbf{y}, \theta))$$

where  $E_{-\theta_i}(\cdot)$  is the expectation with respect to  $\prod_{i\neq j}q_i(\theta_i)$ .

► Equivalent form with full conditionals

$$q_i(\theta) \propto \exp\left(E_{-\theta_i} \ln p(\theta_i | \theta_{-i}, \mathbf{y})\right)$$

#### COORDINATE ASCENT VARIATIONAL INFERENCE

#### Algorithm 1: Coordinate Ascent Variational Inference (CAVI)

Input: A model  $p(x, \theta)$ , a data set x, initial variational factors  $q_j(\theta_j)$  while ELBO has not converged do

```
\begin{array}{l} \text{for } j \in \{1,...,p\} \text{ do} \\ \mid \text{ Set } q_j(\theta_j) \propto \exp\{\mathbb{E}_{-j}p(\theta_j|\theta_{-j},\mathbf{x})\} \\ \text{end} \\ \text{Compute ELBO}(q) = \mathbb{E}[\log p(\mathbf{x},\theta)] + \mathbb{E}[\log q(\theta)] \end{array}
```

end

**Output:** A mean-field variational density  $q(\theta) = \prod_{j=1}^p q_j(\theta_j)$ 

- ▶ Optimal  $q_i(\theta)$  often turn out to be parametric (normal, gamma etc).
- ▶ Updates become just an **updating of variational hyperparameters**.
- ► See [2] for details for exponential families.

#### MEAN-FIELD VI - BIVARIATE NORMAL

Bivariate normal model:

$$\left(\begin{array}{c} \mathbf{x}_{1i} \\ \mathbf{x}_{2i} \end{array}\right) \overset{\mathit{iid}}{\sim} \textit{N}\left[\left(\begin{array}{c} \mu_1 \\ \mu_2 \end{array}\right), \rho \textit{I}\right], \ \textit{i} = 1, ..., \textit{n}$$

where  $\rho$  is known. Indep normal prior.

Prior:

$$\left(\begin{array}{c} \mu_1 \\ \mu_2 \end{array}\right) \stackrel{\textit{iid}}{\sim} \textit{N}\left[\left(\begin{array}{c} 0 \\ 0 \end{array}\right), 0.25^2\textit{I}\right].$$

Exact posterior by well known formulas:

$$\begin{pmatrix} \mu_1 \\ \mu_2 \end{pmatrix} | \mathbf{x}_1, ..., \mathbf{x}_n \stackrel{iid}{\sim} \mathcal{N}\left(\tilde{\mu}, \tilde{\Omega}^{-1}\right),$$

where

$$\tilde{\Omega} = \begin{pmatrix} \omega_1^2 & \omega_{12} \\ \omega_{12} & \omega_2^2 \end{pmatrix}.$$

#### Mean-field VI - Bivariate Normal

► Exact posterior by well known formulas:

$$\begin{pmatrix} \mu_1 \\ \mu_2 \end{pmatrix} | \mathbf{x}_1, ..., \mathbf{x}_n \stackrel{iid}{\sim} N\left(\mathbf{m}, \Omega^{-1}\right),$$

where

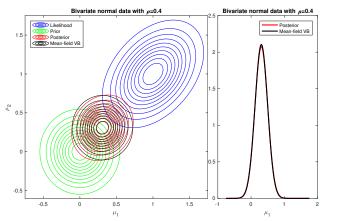

$$\Omega = \left( \begin{array}{cc} \omega_1^2 & \omega_{12} \\ \omega_{12} & \omega_2^2 \end{array} \right).$$

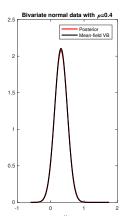

- ▶ Mean-field approximation:  $q(\mu_1, \mu_2) = q_1(\mu_1)q_2(\mu_2)$ .
- ▶ Find optimal mean-field VI solution by iterating on  $\tilde{\mu}_1$  and  $\tilde{\mu}_2$ :

$$\begin{split} q_1^\star(\mu_1) &\propto \exp\left[E_{q_2(\mu_2)} \ln p(\mu_1|\mu_2,\mathbf{x})\right] = N\left(\tilde{\mu}_1,\frac{1}{\omega_1^2}\right) \\ q_2^\star(\mu_2) &\propto \exp\left[E_{q_1(\mu_1)} \ln p(\mu_2|\mu_1,\mathbf{x})\right] = N\left(\tilde{\mu}_2,\frac{1}{\omega_2^2}\right) \end{split}$$

where  $\tilde{\mu}_1=m_1-\frac{\omega_{12}}{\omega_1^2}(\tilde{\mu}_2-m_2)$  and  $\tilde{\mu}_2=m_2-\frac{\omega_{12}}{\omega_2^2}(\tilde{\mu}_1-m_1)$ .

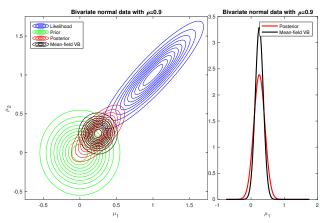

# Mean-field VI - Normal data with ho = 0.4

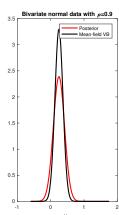

# Mean-field VI - Normal data with ho = 0.9

# MEAN-FIELD VI - UNIVARIATE NORMAL DATA WITH UNKNOWN VARIANCE

- ▶ Model:  $X_i | \theta, \sigma^2 \stackrel{iid}{\sim} N(\theta, \sigma^2)$ .
- ▶ Prior:  $\theta \sim N(\mu_0, \tau_0^2)$  independent of  $\sigma^2 \sim Inv \chi^2(\nu_0, \sigma_0^2)$ .
- ▶ Mean-field approximation:  $q(\theta, \sigma^2) = q_{\theta}(\theta) \cdot q_{\sigma^2}(\sigma^2)$ .
- Optimal densities

$$\begin{split} q_{\theta}^*(\theta) &\propto \exp\left[E_{q(\sigma^2)} \ln p(\theta, \sigma^2, \mathbf{x})\right] \\ q_{\sigma^2}^*(\sigma^2) &\propto \exp\left[E_{q(\theta)} \ln p(\theta, \sigma^2, \mathbf{x})\right] \end{split}$$

#### NORMAL MODEL - VI ALGORITHM

▶ Variational density for  $\sigma^2$ 

$$\sigma^2 \sim Inv - \chi^2 \left( \tilde{v}_n, \tilde{\sigma}_n^2 \right)$$

where 
$$\tilde{v}_n = v_0 + n$$
 and  $\tilde{\sigma}_n = \frac{v_0 \sigma_0^2 + \sum_{i=1}^n (x_i - \tilde{\mu}_n)^2 + n \cdot \tilde{\tau}_n^2}{v_0 + n}$ 

▶ Variational density for  $\theta$ 

$$\theta \sim N\left(\tilde{\mu}_n, \tilde{\tau}_n^2\right)$$

where

$$\tilde{\tau}_n^2 = \frac{1}{\frac{n}{\tilde{\sigma}_n^2} + \frac{1}{\tau_0^2}}$$

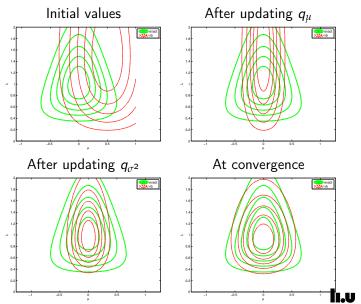

$$\tilde{\mu}_n = \tilde{w}\bar{x} + (1 - \tilde{w})\mu_0,$$

where

$$\tilde{w} = \frac{\frac{n}{\tilde{\sigma}_n^2}}{\frac{n}{\tilde{\sigma}_n^2} + \frac{1}{\tau_0^2}}$$

# NORMAL EXAMPLE FROM MURPHY [3] ( $\lambda = 1/\sigma^2$ )

#### PROBIT REGRESSION

Model:

$$\Pr\left(y_i = 1 | \mathbf{x}_i\right) = \Phi(\mathbf{x}_i^T \boldsymbol{\beta})$$

- ▶ **Prior**:  $\beta \sim N(0, \Sigma_{\beta})$ . For example:  $\Sigma_{\beta} = \tau^2 I$ .
- Latent variable formulation with  $u = (u_1, ..., u_n)'$

$$\mathbf{u}|\beta \sim \textit{N}(\mathbf{X}\beta,1)$$

and

$$y_i = \begin{cases} 0 & \text{if } u_i \le 0 \\ 1 & \text{if } u_i > 0 \end{cases}$$

Factorized variational approximation

$$q(\mathbf{u}, \beta) = q_{\mathbf{u}}(\mathbf{u})q_{\beta}(\beta)$$

## VI FOR PROBIT REGRESSION [1]

VI posterior

$$eta \sim extstyle N \left( ilde{\mu}_eta, \left( extstyle extstyle extstyle extstyle extstyle ( extstyle ex$$

where

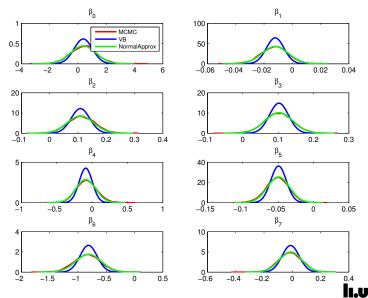

$$ilde{\mu}_{eta} = \left( \mathbf{X}^{T} \mathbf{X} + \Sigma_{eta}^{-1} 
ight)^{-1} \mathbf{X}^{T} ilde{\mu}_{\mathbf{u}}$$

and

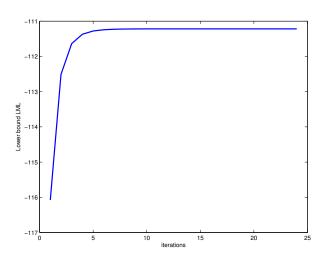

$$\tilde{\mu}_{\mathbf{u}} = \mathbf{X} \tilde{\boldsymbol{\mu}}_{\boldsymbol{\beta}} + \frac{\phi \left( \mathbf{X} \tilde{\boldsymbol{\mu}}_{\boldsymbol{\beta}} \right)}{\Phi \left( \mathbf{X} \tilde{\boldsymbol{\mu}}_{\boldsymbol{\beta}} \right)^{\mathbf{y}} \left[ \Phi \left( \mathbf{X} \tilde{\boldsymbol{\mu}}_{\boldsymbol{\beta}} \right) - \mathbf{1}_{n} \right]^{\mathbf{1}_{n} - \mathbf{y}}}.$$

## PROBIT EXAMPLE (N=200 OBSERVATIONS)

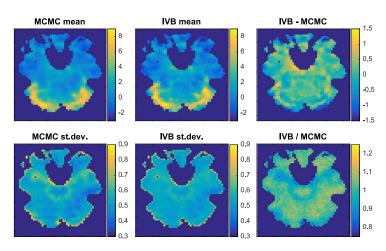

#### PROBIT EXAMPLE - ELBO

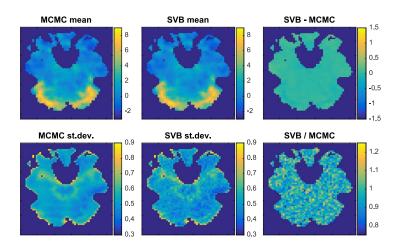

# SPATIAL NEUROIMAGING - MCMC VS MEAN-FIELD [4]

## SPATIAL NEUROIMAGING - MCMC vs VI [4]

## VI FOR LATENT VARIABLE MODELS [2]

Example: Normal mixture model

$$p(x_i) = \sum_{k=1}^K \pi_k N(\mu_k, \sigma_k^2)$$

$$z_i \sim \text{Categorical}(\pi_1, ... \pi_K)$$
 and  $x_i | z_i \stackrel{\text{indep}}{\sim} N(\mu_{z_i}, \sigma_{z_i}^2)$ 

- ▶ Global variables (parameters):  $\theta = (\mu_{1:K}, \sigma_{1:K}, \pi_{1:K})^T$
- ▶ Local parameters (latent variables):  $\mathbf{z} = (z_1, ..., z_n)^T$ .
- ► CAVI:
  - (for i = 1,...n) Update  $q_{\varphi_i}(z_i)$  wrt local variational parameters  $\varphi_i$
  - Update  $q_{\lambda}(\theta)$  wrt global variational parameter  $\lambda$
- Explicit updates for exponential family models.
- ▶ Slow for large *n*.

## CAVI FOR MIXTURE OF NORMALS [2]

#### Algorithm 2: CAVI for a Gaussian mixture model **Input**: Data $x_{1:n}$ , number of components K, prior variance of component means $\sigma^2$ **Output**: Variational densities $q(\mu_k; m_k, s_k^2)$ (Gaussian) and $q(z_i; \varphi_i)$ (*K*-categorical) **Initialize:** Variational parameters $\mathbf{m} = m_{1:K}$ , $\mathbf{s}^2 = s_{1:K}^2$ , and $\varphi = \varphi_{1:n}$ while the ELBO has not converged do for $i \in \{1, ..., n\}$ do Set $\varphi_{ik} \propto \exp\{\mathbb{E}[\mu_k; m_k, s_k^2]x_i - \mathbb{E}[\mu_k^2; m_k, s_k^2]/2\}$ end for $k \in \{1, ..., K\}$ do Set $m_k \leftarrow \frac{\sum_i \varphi_{ik} x_i}{1/\sigma^2 + \sum_i \varphi_{ik}}$ Set $s_k^2 \leftarrow \frac{1}{1/\sigma^2 + \sum_i \varphi_{ik}}$ end Compute ELBO( $\mathbf{m}, \mathbf{s}^2, \boldsymbol{\varphi}$ ) end return $q(\mathbf{m}, \mathbf{s}^2, \boldsymbol{\varphi})$

## STOCHASTIC VARIATIONAL INFERENCE (SVI) [5]

- Conditionally conjugate models with (local) latent variables.
- $\blacktriangleright$  Aim: variational approximation for global variables  $\theta$ .
- ► Coordinate ascent is replaced by gradient-based optimization.
- ► CAVI + Stochastic optimization with noisy gradients
- ▶ Unbiased estimate of the gradient from a minibatch of observations.
- ▶ Only need to update the variational for latents corresponding to observations in the minibatch. Fast.

#### BLACK BOX VARIATIONAL INFERENCE (BBVI)

- ▶ Mean-field makes Q conveniently small, but the approximation can be poor. Especially for the variance.
- ▶ Recent push to use more expressive  $q \in \mathcal{Q}$  approximations. Harder optimization.  $\mathbb{E}_q$  often intractable.
- ► BBVI also called doubly-stochastic:
  - 1. BBVI approximates  $\mathbb{E}_q$  by Monte Carlo integration.
  - Gradient-based stochastic optimization with unbiased estimates of the gradients.

# BLACK BOX VARIATIONAL INFERENCE (BBVI)[6]

- Assume:  $q_{\mu,\mathbf{C}}(\theta) = N(\theta|\mu,\mathbf{CC}^T)$ . Optimize over  $\mu \in \mathbb{R}^p$  and  $\mathbf{C}$ , a lower-triangular positive definite matrix.
- ▶ More generally, assume VI approximation of  $p(\theta|\mathbf{x}) \approx q_{\mu,\mathbf{C}}(\theta)$  from correlating a standard random vector  $\mathbf{z}$  with density  $\phi(\mathbf{z})$

$$\theta = \mu + Cz$$
.

- ► Example: if  $\mathbf{z} \sim N(\mathbf{0}, \mathbf{I})$ , then  $q_{\mu, \mathbf{C}}(\theta) = N(\theta | \mu, \mathbf{CC}^T)$ .
- ► Generally, by the change-of-variable formula

$$q_{\mu,\mathbf{C}}(\theta) = \frac{1}{|\mathbf{C}|} \phi \left( \mathbf{C}^{-1}(\theta - \mu) \right)$$

▶ Using the change of variable formula:

$$\begin{aligned} \text{ELBO}(\mu, \mathbf{C}) &= \mathbb{E}_{q(\theta)} \log p(\mathbf{x}, \theta) - \mathbb{E}_{q(\theta)} \log q(\theta) \\ &= \mathbb{E}_{\phi(\mathbf{z})} \log p(\mathbf{x}, \mu + \mathbf{C}\mathbf{z}) + \log |\mathbf{C}| + H_{\phi}, \end{aligned}$$

where  $\log \mathbf{C} = \sum_{j=1}^p \log C_{jj}$  and  $H_{\phi}$  is the entropy of  $\phi(\mathbf{z})$ , which is constant wrt  $\mu$  and  $\mathbf{C}$ .

## BLACK BOX VARIATIONAL INFERENCE (BBVI)[6]

► From previous slide:

$$\mathrm{ELBO}(\mu, \mathbf{C}) = \mathbb{E}_{\phi(\mathbf{z})} \log p(\mathbf{x}, \mu + \mathbf{C}\mathbf{z}) + \log |\mathbf{C}| + H_{\phi}.$$

▶ Gradient-based optimization. Swapping order of  $\nabla$  and  $\mathbb{E}$ .

$$\begin{split} & \nabla_{\mu} \text{ELBO}(\mu, \mathbf{C}) = \mathbb{E}_{\phi(\mathbf{z})} \left[ \nabla_{\mu} \log p(\mathbf{x}, \mu + \mathbf{C} \mathbf{z}) \right] \\ & \nabla_{\mathbf{C}} \text{ELBO}(\mu, \mathbf{C}) = \mathbb{E}_{\phi(\mathbf{z})} \left[ \nabla_{\mathbf{C}} \log p(\mathbf{x}, \mu + \mathbf{C} \mathbf{z}) \right] + \Delta_{\mathbf{C}} \end{split}$$

where  $\Delta_{\mathbf{C}} \equiv \operatorname{diag}(1/c_{11},...,1/c_{pp})$  and  $\nabla_{\mathbf{C}} \log p(\mathbf{x}, \mu + \mathbf{C}\mathbf{z})$  a lower triangular matrix with partial derivatives.

 $\blacktriangleright$  We can change back to  $\theta$  to get alternative expressions:

$$\nabla_{\mu} \text{ELBO}(\mu, \mathbf{C}) = \mathbb{E}_{q(\theta|\mu, \mathbf{C})} \left[ \nabla_{\theta} \log p(\mathbf{x}, \theta) \right]$$

$$\nabla_{\mathbf{C}} \text{ELBO}(\mu, \mathbf{C}) = \mathbb{E}_{q(\theta|\mu, \mathbf{C})} \left[ \nabla_{\theta} \log p(\mathbf{x}, \theta) (\theta - \mu)^{T} \mathbf{C}^{-T} \right] + \Delta_{\mathbf{C}}$$

where  $\nabla_{\theta} \log p(\mathbf{x}, \theta) \mathbf{z}^T$  is the lower triangular part after outer product.

#### DOUBLY STOCHASTIC VARIATIONAL INFERENCE [6]

#### Algorithm 2: Doubly Stochastic Variational Inference (DSVI)

**Input:** A gradient function  $\nabla_{\theta} \log p(\mathbf{x}, \theta)$ , a simulator  $\phi(\mathbf{z})$ , a data set  $\mathbf{x}$ , initial values  $\mu^0$ ,  $\mathbf{C}^0$ , learning rate  $\{\rho_t\}_{t\geq 1}$ .

Set 
$$t = 0$$

while convergence criterion not met do

$$\begin{aligned} & t = t + 1 \\ & \mathbf{z} \sim \phi(\mathbf{z}) \\ & \theta^{(t-1)} = \mathbf{C}^{(t-1)} \mathbf{z} + \mu^{(t-1)} \\ & \mu^{(t)} = \mu^{(t-1)} + \rho_t \nabla_{\theta} \log p(\mathbf{x}, \theta^{(t-1)}) \\ & \mathbf{C}^{(t)} = \mathbf{C}^{(t-1)} + \rho_t \left( \nabla_{\theta} \log p(\mathbf{x}, \theta^{(t-1)}) \times \mathbf{z}^T + \Delta_{\mathbf{C}^{(t-1)}} \right) \end{aligned}$$

end

**Output:** Optimal variational parameters  $\mu^*$  and  $C^*$ .

#### **EXTENSIONS OF BBVI**

- ▶ Replacing covariance matrix  $\mathbf{CC}^T$  in  $q_{\mu,\mathbf{C}}(\theta) = N(\theta|\mu,\mathbf{CC}^T)$  by sparse precision matrix [7]. Very useful for models with sparse conditional dependence structure. Spatial. State-space.
- ▶ Modeling the variational covariance matrix by factor structure. [8]
- ▶ Variational autoencoders.  $q_{\mu,C}(\theta) = N(\theta|\mu(\mathbf{x}), \Sigma(\mathbf{x}))$ , where mean and covariance is a deep neural network. [9]
